Warning

Although this wrapper is capable of reading files stores in HDFS, Amazon S3, Azure Blob Storage and Azure Data Lake Storage, the technical artifacts of this wrapper include HDFS in their names for legacy compatibility:

- Jars: denodo-hdfs-custom-wrapper-xxx
- Wrappers: com.denodo.connect.hadoop.hdfs.wrapper.HDFSxxxFileWrapper

1 INTRODUCTION

The Distributed File System Custom Wrapper distribution contains five Virtual DataPort custom wrappers capable of reading several file formats stored in HDFS, Amazon S3, Azure Blob Storage and Azure Data Lake Storage.

Supported formats are:

- Delimited text files
- Sequence files
- Map files
- Avro files
- Parquet files

1.1 DELIMITED TEXT FILES

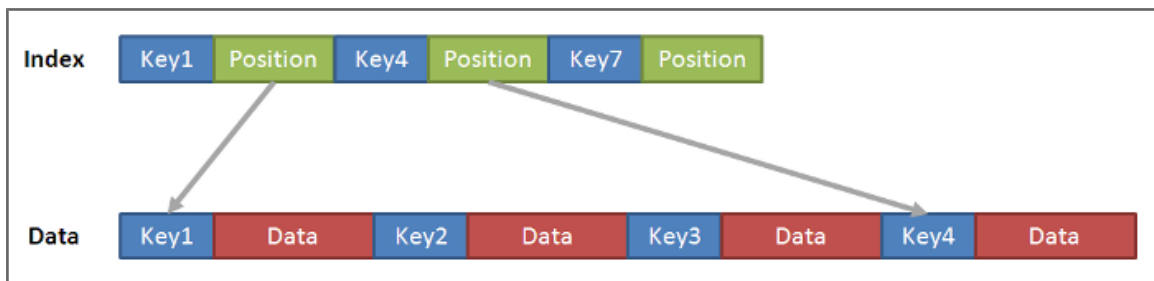

Delimited text files store plain text and each line has values separated by a delimiter, such as tab, space, comma, etc.

1.2 SEQUENCEFILES

Sequence files are binary record-oriented files, where each record has a serialized key and a serialized value.

1.3 MAPFILES

A map is a directory containing two sequence files. The data file (/data) is identical to the sequence file and contains the data stored as binary key/value pairs. The index file (/index), which contains a key/value map with seek positions inside the data file to quickly access the data.

Map file format

1.4 AVRO FILES

Avro data files are self-describing, containing the full schema for the data in the file. An Avro schema is defined using JSON. The schema allows you to define two types of data:

- primitive data types: string, integer, long, float, double, byte, null and boolean.
- complex type definitions: a record, an array, an enum, a map, a union or a

fixed type.

```
{ "namespace": "example.avro",  
  "type": "record",  
  "name": "User",  
  "fields":  
    [  
      { "name": "name", "type": "string" },  
      { "name": "favorite_number", "type": [ "int", "null" ] },  
      { "name": "favorite_color", "type": [ "string", "null" ] }  
    ]  
}
```

Avro schema

1.5 PARQUET FILES

Parquet is a column-oriented data store of the Hadoop ecosystem. It provides data compression on a per-column level and encoding schemas.

The data are described by a schema that starts with the word *Message* and contains a group of fields. Each field is defined by a *repetition* (required, optional, or repeated), a *type* and a *name*.

```
Message Customer {  
  required int32 id;  
  required binary firstname (UTF8);  
  required binary lastname (UTF8);  
}
```

Parquet schema

Primitives types in parquet are boolean, int32, int64, int96, float, double, binary and fixed_len_byte_array. There are no String types but there are logical types which allows interpreting binaries as a String, JSON or other types.

Complex types are defined by a group type, which adds a layer of nesting.

2 USAGE

The Distributed File System Custom Wrapper distribution consists of:

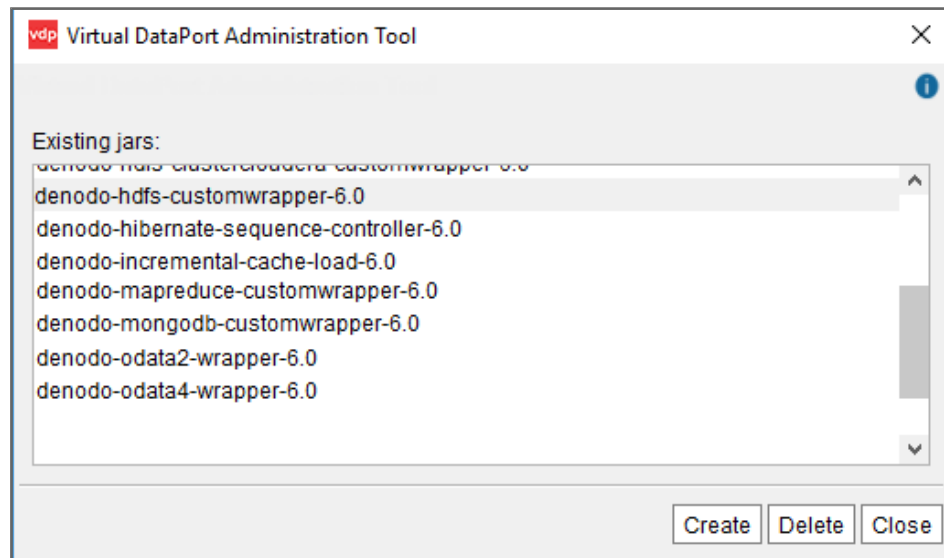

- /conf: A folder containing a sample core-site.xml file with properties you might need commented out.
- /dist:
 - denodo-hdfs-customwrapper-\${version}.jar. The custom wrapper.
 - denodo-hdfs-customwrapper-\${version}-jar-with-dependencies.jar. The custom wrapper plus its dependencies. This is the wrapper we recommend to use, as it is easier to install in VDP.
- /doc: A documentation folder containing this user manual
- /lib: All the dependencies required by this wrapper in case you need to use the denodo-hdfs-customwrapper-\${version}.jar

2.1 IMPORTING THE CUSTOM WRAPPER INTO VDP

In order to use the Distributed File System Custom Wrapper in VDP, we must configure the Admin Tool to import the extension.

From the Distributed File System Custom Wrapper distribution, we will select the **denodo-hdfs-customwrapper-\${version}-jar-with-dependencies.jar** file and upload it to VDP.

No other jars are required as this one will already contain all the required dependencies.

Distributed File System extension in VDP

2.2 CREATING A DISTRIBUTED FILE SYSTEM DATA SOURCE

Once the custom wrapper jar file has been uploaded to VDP using the Admin Tool, we can create new data sources for this custom wrapper --and their corresponding base views-- as usual.

Go to New → Data Source → Custom and specify one of the possible wrappers:

- `com.denodo.connect.hadoop.hdfs.wrapper.HDFSDelimitedTextFileWrapper`
- `com.denodo.connect.hadoop.hdfs.wrapper.HDFSSequenceFileWrapper`
- `com.denodo.connect.hadoop.hdfs.wrapper.HDFSMapFileWrapper`
- `com.denodo.connect.hadoop.hdfs.wrapper.HDFSAvroFileWrapper`
- `com.denodo.connect.hadoop.hdfs.wrapper.WebHDFSFileWrapper`
(deprecated)
- `com.denodo.connect.hadoop.hdfs.wrapper.HDFSParquetFileWrapper`

Also check 'Select Jars' and choose the jar file of the custom wrapper.

Distributed File System Data Source

2.3 CREATING A BASE VIEW

Once the custom wrapper has been registered, we will be asked by VDP to create a base view for it.

2.3.1 HDFSDelimitedTextFileWrapper

Custom wrapper for reading delimited text files. Its base views need the following parameters:

- **File system URI:** A URI whose scheme and authority identify the file system.
 - **HDFS:** `hdfs://<ip>:<port>`.

- **Amazon S3:** `s3a://@<bucket>`. For configuring the credentials see **Amazon S3** section.
- **Azure Data Lake Store:**
`adl://<account name>.azuredatalakestore.net/`
For configuring the credentials see **Azure Data Lake Store** section.
- **Azure Blob Storage:**
`wasb://<container>@<account>.blob.core.windows.net`
For configuring the credentials see **Azure Blob Storage** section.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the URI contains @ you have to enter \@.

- **Path:** input path for the delimited file or the directory containing the files.
- **File name pattern:** If you want this wrapper to only obtain data from some of the files of the directory, you can enter a regular expression that matches the names of these files.
For example, if you want the base view to return the data of all the files with the extension csv set the File name pattern to `(.*)\\.csv`, (notice that the regular expression is escaped as explained in the note below). Optional.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the File name pattern contains \ you have to enter \\.

- **Delete after reading:** Requests that the file or directory denoted by the path be deleted when the wrapper terminates.
- **Custom core-site.xml file:** configuration file that overrides the default core parameters. Optional.
- **Custom hdfs-site xml file:** configuration file that overrides the default HDFS parameters. Optional.
- **Separator:** delimiter between the values of a row. Default is the comma (,) and cannot be a line break (\n or \r). Optional.

Some “invisible” characters have to be entered in a special way:

Character	Meaning
\t	Tab
\f	Formfeed

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the separator is the tab character \t you have to enter \\t.

- **Quote:** Character used to encapsulate values containing special characters. Default is quote ("). Optional.
- **Comment marker:** Character marking the start of a line comment. Comments are disabled by default. Optional.
- **Escape:** Escape character. Escapes are disabled by default. Optional.
- **Ignore spaces:** Whether spaces around values are ignored. False by default.
- **Header:** If selected, the wrapper considers that the first line contains the names of the fields in this file. These names will be the fields' names of the base views created from this wrapper. True by default.

2.3.2 HDFSSequenceFileWrapper

Custom wrapper for reading sequence files. Its base views need the following parameters:

- **File system URI:** A URI whose scheme and authority identify the file system.
 - **HDFS:** `hdfs://<ip>:<port>`.
 - **Amazon S3:** `s3a://@<bucket>`. For configuring the credentials see **Amazon S3** section.
 - **Azure Data Lake Store:**
`adl://<account name>.azuredatalakestore.net/`
For configuring the credentials see **Azure Data Lake Store** section.
 - **Azure Blob Storage:**
`wasb://<container>@<account>.blob.core.windows.net`
For configuring the credentials see **Azure Blob Storage** section.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the URI contains @ you have to enter \@.

- **Path:** input path for the sequence file or the directory containing the files.
- **File name pattern:** If you want this wrapper to only obtain data from some of the files of the directory, you can enter a regular expression that matches the names of these files.
For example, if you want the base view to return the data of all the files with the extension seq set the File name pattern to `(.*)\\.seq`, (notice that the regular expression is escaped as explained in the note below). Optional.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the File name pattern contains \ you have to enter \\.

- **Delete after reading:** Requests that the file or directory denoted by the path be deleted when the wrapper terminates.

- **Custom core-site.xml file:** configuration file that overrides the default core parameters. Optional.
- **Custom hdfs-site.xml file:** configuration file that overrides the default HDFS parameters. Optional.
- **Key class:** key class name implementing org.apache.hadoop.io.Writable interface.
- **Value class:** value class name implementing org.apache.hadoop.io.Writable interface.

2.3.3 HDFSMapFileWrapper

Custom wrapper for reading map files. Its base views need the following parameters:

- **File system URI:** A URI whose scheme and authority identify the file system.
 - **HDFS:** `hdfs://<ip>:<port>`.
 - **Amazon S3:** `s3a://@<bucket>`. For configuring the credentials see **Amazon S3** section.
 - **Azure Data Lake Store:** `adl://<account name>.azuredatalakestore.net/`
For configuring the credentials see **Azure Data Lake Store** section.
 - **Azure Blob Storage:** `wasb://<container>@<account>.blob.core.windows.net`
For configuring the credentials see **Azure Blob Storage** section.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the URI contains @ you have to enter \@.

- **Path:** input path for the directory containing the map file. Also the path to the index or data file could be specified. When using **Amazon S3**, a flat file system where there is no folder concept, **the path to the index or data should be used**.

- **File name pattern:** If you want this wrapper to only obtain data from some of the files of the directory, you can enter a regular expression that matches the names of these files.
For example, if you want the base view to return the data of all the files with the extension whatever set the File name pattern to `(.*)\\\.whatever`, (notice that the regular expression is escaped as explained in the note below). Optional.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables `@`, `\`, `^`, `{`, `}`, you have to escape these characters with `\`.

E.g if the File name pattern contains `\` you have to enter `\\`.

- **Delete after reading:** Requests that the file or directory denoted by the path be deleted when the wrapper terminates.
- **Custom core-site.xml file:** configuration file that overrides the default core parameters. Optional.
- **Custom hdfs-site xml file:** configuration file that overrides the default HDFS parameters. Optional.
- **Key class:** key class name implementing the `org.apache.hadoop.io.WritableComparable` interface. `WritableComparable` is used because records are sorted in **key order**.
- **Value class:** value class name implementing the `org.apache.hadoop.io.Writable` interface.

2.3.4 HDFSAvroFileWrapper

Custom wrapper for reading Avro files.

Important

We recommend not to use the HDFSAvroFileWrapper to directly access Avro files, as this is an internal serialization system mainly meant for use by applications running on the Hadoop cluster. Instead, we recommend to use an abstraction layer on top of those files like e.g. Hive, Impala, Spark...

Its base views need the following parameters:

- **File system URI:** A URI whose scheme and authority identify the file system.
 - **HDFS:** `hdfs://<ip>:<port>`.
 - **Amazon S3:** `s3a://<bucket>`. For configuring the credentials see **Amazon S3** section.
 - **Azure Data Lake Store:**
`adl://<account name>.azuredatalakestore.net/`
For configuring the credentials see **Azure Data Lake Store** section.
 - **Azure Blob Storage:**
`wasb://<container>@<account>.blob.core.windows.net`
For configuring the credentials see **Azure Blob Storage** section.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the URI contains @ you have to enter \@.

- **File name pattern:** If you want this wrapper to only obtain data from some of the files of the directory, you can enter a regular expression that matches the names of these files.
For example, if you want the base view to return the data of all the files with the extension avro set the File name pattern to (.*)\.avro, (notice that the regular expression is escaped as explained in the note below). Optional.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the File name pattern contains \ you have to enter \.

- **Delete after reading:** Requests that the file denoted by the path be deleted when the wrapper terminates.
- **Custom core-site.xml file:** configuration file that overrides the default core parameters. Optional.
- **Custom hdfs-site xml file:** configuration file that overrides the default HDFS parameters. Optional.

There is also two parameters that are **mutually exclusive**:

- **Avro schema path:** input path for the Avro schema file or
- **Avro schema JSON:** JSON of the Avro schema.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, } in the **Avro schema JSON** parameter, you have to escape these characters with \. For example:

\{

```
"type": "map",
  "values": \{
    "type": "record",
    "name": "ATM",
    "fields": [
      \{ "name": "serial_no", "type": "string" \},
      \{ "name": "location", "type": "string" \}
    ]
  }
}
```

File system URI	<input type="text" value="hdfs://quickstart.cloudera:8020"/>		
Avro schema path	<input type="text" value="/user/cloudera/avro/RecordWithAllTypes.avsc"/>		
Avro schema JSON	<input type="text"/>		
File name pattern	<input type="text" value="(.*)\\.avro"/>		
	<input type="checkbox"/> Delete after reading		
Custom core-site.xml file	<input type="text" value="None"/>	<input type="button" value="▼"/>	<input type="button" value="Configure"/>
Custom hdfs-site.xml file	<input type="text" value="None"/>	<input type="button" value="▼"/>	<input type="button" value="Configure"/>
	<input type="checkbox"/> Kerberos enabled		
Kerberos principal name	<input type="text"/>		
Kerberos keytab file	<input type="text" value="None"/>	<input type="button" value="▼"/>	<input type="button" value="Configure"/>
Kerberos password	<input type="text"/>

2.3.4.1 Field Projection

The recommended way for dealing with **projections** in HDFSAvroFileWrapper is by means of the JSON schema parameters:

- Avro schema path or
- Avro schema JSON

By giving to the wrapper a JSON schema containing exclusively the fields we are interested in, the reader used by the HDFSAvroFileWrapper will return to VDP only these fields, making the select operation faster.

If we configure the parameter Avro schema JSON with only some of the fields of the /user/cloudera/schema.avsc file used in the previous example, like in the example below (notice the escaped characters):

```
\{
  "type" : "record",
  "name" : "Doc",
  "doc" : "adoc",
  "fields" : [ \{
    "name" : "id",
    "type" : "string"
  \}, \{
    "name" : "user_friends_count",
    "type" : [ "int", "null" ]
  \}, \{
    "name" : "user_location",
    "type" : [ "string", "null" ]
  \}, \{
    "name" : "user_followers_count",
    "type" : [ "int", "null" ]
  \}, \{
    "name" : "user_name",

2.3.5 WebHDFSFileWrapper

Warning

WebHDFSFileWrapper is **deprecated**.

- For XML, JSON and Delimited files the best alternative is using the **VDP standard data sources**, using the HTTP Client in its Data route parameter. These data sources offers a better solution for HTTP/HTTPs access as they include proxy access, SPNEGO authentication, OAuth2 etc.
- For Avro, Sequence, Map and Parquet files the best alternative is using the specific custom wrapper type: **HDFSAvroFileWrapper**, **HDFSSequenceFileWrapper**, **HDFSMapFileWrapper** or **HDFSParquetFileWrapper** with webhdfs scheme in their File system URI parameter. And placing their credentials in the xml configuration files.

Custom wrapper for reading delimited text files using the **WebHDFS**.

2.3.5.1 About WebHDFS

WebHDFS provides HTTP REST access to HDFS. It supports all HDFS user operations including reading files, writing to files, making directories, changing permissions and renaming.

The advantage of WebHDFS are:

- **Version-independent** REST-based protocol which means that can be read and written to/from Hadoop clusters no matter their version.
- Read and write data in a cluster behind a firewall. A proxy WebHDFS (for example: HttpFS) could be use, it acts as a gateway and is the only system that is allowed to send and receive data through the firewall.
The only difference between using or not the proxy will be in the host:port pair where the HTTP requests are issued:
 - Default port for WebHDFS is 50070.
 - Default port for HttpFS is 14000.

2.3.5.2 Custom wrapper

The base views created from the WebHDFSFileWrapper need the following parameters:

- **Host IP:** IP or <bucket>.s3.amazonaws.com for Amazon S3.
- **Host port:** HTTP port. Default port for WebHDFS is 50070. For HttpFS is 14000. For Amazon S3 is 80.

- **User:** The name of the the authenticated user when security is off. If is not set, the server may either set the authenticated user to a default web user, if there is any, or return an error response.
When using **Amazon S3** <id>:<secret> should be indicated.
- **Path:** input path for the delimited file.
- **Separator:** delimiter between values. Default is the comma.
- **Quote:** Character used to encapsulate values containing special characters. Default is quote.
- **Comment marker:** Character marking the start of a line comment. Comments are disable by default.
- **Escape:** Escape character. Escapes are disabled by default.
- **Ignore spaces:** Whether spaces around values are ignored. False by default.
- **Header:** Whether the file has a header or not. True by default.
- **Delete after reading:** Requests that the file or directory denoted by the path be deleted when the wrapper terminates.

2.3.6 HDFSParquetFileWrapper

Custom wrapper for reading Parquet files.

Important

We recommend not to use the HDFSParquetFileWrapper to directly access Parquet files, as this is an internal columnar data representation mainly meant for use by applications running on the Hadoop cluster. Instead, we recommend to use an abstraction layer on top of those files like e.g. Hive, Impala, Spark...

Its base views need the following parameters:

- **File system URI:** A URI whose scheme and authority identify the file system.
 - **HDFS:** `hdfs://<ip>:<port>`.
 - **Amazon S3:** `s3a://@<bucket>`. For configuring the credentials see **Amazon S3** section.
 - **Azure Data Lake Store:**
`adl://<account name>.azuredatalakestore.net/`
For configuring the credentials see **Azure Data Lake Store** section.
 - **Azure Blob Storage:**
`wasb://<container>@<account>.blob.core.windows.net`
For configuring the credentials see **Azure Blob Storage** section.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the URI contains @ you have to enter \@.

- **Parquet File Path:** path of the file that we want to read.
- **File name pattern:** If you want this wrapper to only obtain data from some of the files of the directory, you can enter a regular expression that matches the names of these files.
For example, if you want the base view to return the data of all the files with the extension parquet set the File name pattern to `(.*)\\.parquet`, (notice that the regular expression is escaped as explained in the note below). Optional.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the File name pattern contains \ you have to enter \\\.

- **Custom core-site.xml file:** configuration file that overrides the default core parameters. Optional.
- **Custom hdfs-site.xml file:** configuration file that overrides the default HDFS parameters. Optional.

View results

3 AMAZON S3

The Distributed File System Custom Wrapper can access data stored in Amazon S3 with the following Hadoop FileSystem clients:

- S3.
It is deprecated and it is not supported by the new version of this custom wrapper, version 7.0, as it was deleted from Hadoop 3.x versions.
- S3N.
Use S3A instead as S3A client can read all files created by S3N.
S3N is not supported by the new version of this custom wrapper, version 7.0, as it was deleted from Hadoop 3.x versions.
- S3A.
S3A client can read all files created by S3N. **It should be used wherever possible.**

3.1 CONFIGURING S3 AUTHENTICATION PROPERTIES

Place the credentials in the wrapper configuration file `Custom core-site.xml`. You can use the `core-site.xml`, located in the `conf` folder of the distribution, as a guide.

```
<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="configuration.xsl"?>

<configuration>

<property>
  <name>fs.s3.awsAccessKeyId</name>
  <description>AWS access key ID</description>
  <value>YOUR ACCESS KEY ID</value>
</property>

<property>
  <name>fs.s3.awsSecretAccessKey</name>
  <description>AWS secret key</description>
  <value>YOUR SECRET ACCESS KEY</value>
</property>

</configuration>
```

Alternatively, you could place the credentials in the URI `s3://ID:SECRET@BUCKET/` but this method is discouraged as they will end up in logs and error messages that untrusted people could read.

3.2 CONFIGURING S3N AUTHENTICATION PROPERTIES

Place the credentials in the wrapper configuration file `Custom core-site.xml`. You can use the `core-site.xml`, located in the `conf` folder of the distribution, as a guide.

```
<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="configuration.xsl"?>

<configuration>

<property>
  <name>fs.s3n.awsAccessKeyId</name>
  <description>AWS access key ID</description>
  <value>YOUR ACCESS KEY ID</value>
</property>

<property>
  <name>fs.s3n.awsSecretAccessKey</name>
  <description>AWS secret key</description>
  <value>YOUR SECRET ACCESS KEY</value>
</property>

</configuration>
```

Alternatively, you could place the credentials in the URI `s3n://ID:SECRET@BUCKET/` but this method is discouraged as they will end up in logs and error messages that untrusted people could read.

3.3 CONFIGURING S3A AUTHENTICATION PROPERTIES

S3A supports several authentication mechanisms. By default the custom wrapper will **search for credentials in the following order**:

1. In the Hadoop configuration files.

For using this authentication method, declare the credentials in the wrapper configuration file `Custom core-site.xml`. You can use the `core-site.xml`, located in the `conf` folder of the distribution, as a guide.

```
<configuration>

<property>
  <name>fs.s3a.access.key</name>
  <description>AWS access key ID.</description>
  <value>YOUR ACCESS KEY ID</value>
</property>

<property>
  <name>fs.s3a.secret.key</name>
  <description>AWS secret key.</description>
  <value>YOUR SECRET ACCESS KEY</value>
</property>

</configuration>
```

2. Then, the environment variables named `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` are looked for.
3. Otherwise, an attempt is made to query the Amazon EC2 Instance Metadata Service to retrieve credentials published to EC2 VMs. **This mechanism is available only when running your application on an Amazon EC2 instance, but provides the greatest ease of use and best security** when working with Amazon EC2 instances.

Alternatively, you could place the credentials in the URI `s3a://ID:SECRET@BUCKET/` but this method is discouraged as they will end up in logs and error messages that untrusted people could read.

3.3.1 Using IAM Assumed Roles

To use assumed roles, the wrapper must be configured to use the Assumed Role Credential Provider, `org.apache.hadoop.fs.s3a.auth.AssumedRoleCredentialProvider`, in the configuration option `fs.s3a.aws.credentials.provider` **in the wrapper configuration file `Custom core-site.xml`**.

This Assumed Role Credential provider will read in the `fs.s3a.assumed.role.*` options needed to connect to the Session Token Service Assumed Role API:

1. First authenticating with the full credentials. This means the normal `fs.s3a.access.key` and `fs.s3a.secret.key` pair, environment variables, or some other supplier of long-lived secrets.

The default is the `fs.s3a.access.key` and `fs.s3a.secret.key` pair. If you wish to use a different authentication mechanism, other than `org.apache.hadoop.fs.s3a.SimpleAWSCredentialsProvider`, set it in the property `fs.s3a.assumed.role.credentials.provider`.

2. Then assuming the specific role specified in `fs.s3a.assumed.role.arn`
3. It will then refresh this login at the configured rate of `fs.s3a.assumed.role.session.duration`.

Below is shown the properties required for configuring IAM Assumed Roles in this custom wrapper, using its configuration file, `Custom core-site.xml`. You can use the `core-site.xml`, located in the `conf` folder of the distribution, as a guide.

```
<configuration>

<property>
  <name>fs.s3a.aws.credentials.provider</name>
  <value>org.apache.hadoop.fs.s3a.AssumedRoleCredentialProvider</value>
```

```

    <value>org.apache.hadoop.fs.s3a.auth.AssumedRoleCredentialProvider</value>
  </property>

  <property>
    <name>fs.s3a.assumed.role.arn</name>
    <description>
      AWS ARN for the role to be assumed. Required if the
      fs.s3a.aws.credentials.provider contains
      org.apache.hadoop.fs.s3a.AssumedRoleCredentialProvider
    </description>
    <value>YOUR AWS ROLE</value>
  </property>

  <property>
    <name>fs.s3a.assumed.role.credentials.provider</name>
    <description>
      List of credential providers to authenticate with the
      STS endpoint and retrieve short-lived role credentials.
      Only used if AssumedRoleCredentialProvider is the AWS credential
      Provider. If unset, uses
      "org.apache.hadoop.fs.s3a.SimpleAWSCredentialsProvider".
    </description>
    <value>org.apache.hadoop.fs.s3a.SimpleAWSCredentialsProvider</value>
  </property>

  <property>
    <name>fs.s3a.assumed.role.session.duration</name>
    <value>30m</value>
    <description>
      Duration of assumed roles before a refresh is attempted.
      Only used if AssumedRoleCredentialProvider is the AWS credential
      Provider.
      Range: 15m to 1h
    </description>
  </property>

  <property>
    <name>fs.s3a.access.key</name>
    <description>AWS access key ID.</description>
    <value>YOUR ACCESS KEY ID</value>
  </property>

  <property>
    <name>fs.s3a.secret.key</name>
    <description>AWS secret key.</description>
    <value>YOUR SECRET ACCESS KEY</value>
  </property>

</configuration>

```

3.4 SIGNATURE VERSION 4 SUPPORT

When the V4 signing protocol is used, AWS requires the explicit region endpoint to be used —hence **S3A** must be configured to use the specific endpoint. This is done in the configuration option `fs.s3a.endpoint` in the `CUSTOM` `core-site.xml` of the wrapper. You can use the `core-site.xml`, located in the `conf` folder of the distribution, as a guide. Otherwise a Bad Request exception could be thrown.

As an example of configuration, the endpoint for S3 Frankfurt is `s3.eu-central-1.amazonaws.com`:

```
<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="configuration.xsl"?>

<configuration>
<property>
  <name>fs.s3a.endpoint</name>
  <description>AWS S3 endpoint to connect to. An up-to-date list is
    provided in the AWS Documentation: regions and endpoints. Without
    this property, the standard region (s3.amazonaws.com) is assumed.
  </description>
  <value>s3.eu-central-1.amazonaws.com</value>
</property>
</configuration>
```

You can find the full list of supported versions for AWS Regions in their website: [Amazon Simple Storage Service \(Amazon S3\)](#).

4 AZURE DATA LAKE STORE

The Distributed File System Custom Wrapper can access data stored in Azure Data Lake Store.

4.1 CONFIGURING AUTHENTICATION PROPERTIES

Place the credentials in the wrapper configuration file `Custom core-site.xml`. You can use the `core-site.xml`, located in the `conf` folder of the distribution, as a guide.

```
<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="configuration.xsl"?>

  <configuration>
    <property>
      <name>fs.adl.oauth2.access.token.provider.type</name>
      <value>ClientCredential</value>
    </property>
    <property>
      <name>fs.adl.oauth2.refresh.url</name>
      <value>YOUR TOKEN ENDPOINT</value>
    </property>
    <property>
      <name>fs.adl.oauth2.client.id</name>
      <value>YOUR CLIENT ID</value>
    </property>
    <property>
      <name>fs.adl.oauth2.credential</name>
      <value>YOUR CLIENT SECRET</value>
    </property>
  </configuration>
```

5 AZURE BLOB STORAGE

The Distributed File System Custom Wrapper can access data stored in Azure Blob Storage.

5.1 CONFIGURING AUTHENTICATION PROPERTIES

Place the credentials in the wrapper configuration file `Custom core-site.xml`. You can use the `core-site.xml`, located in the `conf` folder of the distribution, as a guide.

```
<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="configuration.xsl"?>

<configuration>

  <property>
    <name>fs.azure.account.key.<account>.blob.core.windows.net</name>
    <value>YOUR ACCESS KEY</value>
  </property>

</configuration>
```

6 COMPRESSED FILES

Hadoop is intended for storing large data volumes, so compression becomes a mandatory requirement here. There are different compression formats available like zlib, bzip2, snappy, LZO and LZ4.

Hadoop has native implementations of compression libraries for performance reasons and for non-availability of Java implementations:

Compression format	Java implementation	Native implementation
DEFLATE	Yes	Yes
gzip	Yes	Yes
bzip2	Yes	No
LZO	No	Yes
Snappy	No	Yes

Compression library implementations

For reading compressed files using the Distributed File System Custom Wrapper there are two options:

- Use the Java implementation. In this case the wrapper handles compressed files transparently.
- Use the native implementation:
 - for performance reasons or
 - for non-availability of Java implementationIn this case the wrapper must have Hadoop the native libraries in the `java.library.path`.

7 SECURE CLUSTER WITH KERBEROS

The configuration required for accessing a Hadoop cluster with Kerberos enabled is the same as the one needed to access to the distributed file system and, additionally, the user must supplied the Kerberos credentials.

The Kerberos parameters are:

- **Kerberos enabled:** Check it when accessing a Hadoop cluster with Kerberos enabled. Required.
- **Kerberos principal name:** Kerberos v5 Principal name, e.g. primary/instance@realm. Optional.

! Note

If you enter a literal that contains one of the special characters used to indicate interpolation variables @, \, ^, {, }, you have to escape these characters with \.

E.g if the Kerberos principal name contains @ you have to enter \@.

- **Kerberos keytab file:** Keytab file containing the key of the Kerberos principal. Optional.
- **Kerberos password:** Password associated with the principal. Optional.
- **Kerberos Distribution Center:** Kerberos Key Distribution Center. Optional.

The Distributed File System Custom Wrapper provides **three ways** for accessing a kerberized Hadoop cluster:

1. The client has a valid Kerberos ticket in the **ticket cache** obtained, for example, using the kinit command in the Kerberos Client.
In this case only the Kerberos enabled parameter should be checked. The wrapper would use the Kerberos ticket to authenticate itself against the Hadoop cluster.
2. The client does not have a valid Kerberos ticket in the ticket cache. In this case you should provide the Kerberos principal name parameter and
 - 2.1. Kerberos keytab file parameter or
 - 2.2. Kerberos password parameter.

In all these **three scenarios** the **krb5.conf** file should be present in the file system. Below there is an example of the Kerberos configuration file:

```
[libdefaults]
renew_lifetime = 7d
forwardable = true
default_realm = EXAMPLE.COM
ticket_lifetime = 24h
dns_lookup_realm = false
dns_lookup_kdc = false

[domain_realm]
sandbox.hortonworks.com = EXAMPLE.COM
cloudera = CLOUDERA

[realms]
EXAMPLE.COM = {
    admin_server = sandbox.hortonworks.com
    kdc = sandbox.hortonworks.com
}

CLOUDERA = {
    kdc = quickstart.cloudera
    admin_server = quickstart.cloudera
    max_renewable_life = 7d 0h 0m 0s
    default_principal_flags = +renewable
}

[logging]
default = FILE:/var/log/krb5kdc.log
admin_server = FILE:/var/log/kadmind.log
kdc = FILE:/var/log/krb5kdc.log
```

The algorithm to locate the `krb5.conf` file is the following:

- If the system property `java.security.krb5.conf` is set, its value is assumed to specify the path and file name.
- If that system property value is not set, then the configuration file is looked for in the directory
 - `<java-home>\lib\security` (Windows)
 - `<java-home>/lib/security` (Solaris and Linux)
- If the file is still not found, then an attempt is made to locate it as follows:
 - `/etc/krb5/krb5.conf` (Solaris)
 - `c:\winnt\krb5.ini` (Windows)
 - `/etc/krb5.conf` (Linux)

There is an **exception**. If you are planning to create VDP views that use the **same Key Distribution Center and the same realm** the Kerberos Distribution Center parameter can be provided instead of having the krb5.conf file in the file system.

8 TROUBLESHOOTING

Symptom

Error message: "SIMPLE authentication is not enabled. Available:[TOKEN, KERBEROS]".

Resolution

You are trying to connect to a Kerberos-enabled Hadoop cluster. You should configure the custom wrapper accordingly. See [Secure cluster with Kerberos section](#) for **configuring Kerberos** on this custom wrapper.

Symptom

Error message: "Cannot get Kerberos service ticket: KrbException: Server not found in Kerberos database (7) ".

Resolution

Check that nslookup is returning the fully qualified hostname of the KDC. If not, modify the /etc/hosts of the client machine for the KDC entry to be of the form "IP address fully.qualified.hostname alias".

Symptom

Error message: "Invalid hostname in URI s3n://<id>:<secret>@<bucket>".

Resolution

Check your bucket name: underscores are not permitted.

Also check your secret key, if it contains "/" and "+" symbols they need to be encoded in the URL. This method of **placing credentials in the URL is discouraged**. Configure the credentials on the core-site.xml instead (see **Amazon S3 support** section).

Symptom

Error message: "Error accessing Parquet file: Could not read footer: java.io.IOException: Could not read footer for file FileStatus{path=hdfs://serverhdfs/apps/hive/warehouse/parquet/.hive-staging_hive_2017-03-06_08-/-ext-10000; isDirectory=true; modification_time=1488790684826; access_time=0; owner=hive; group=hdfs; permission=rwxr-xr-x; isSymlink=false}"

Resolution

Hive could store metadata into a parquet file folder. You can check in the error message, if the custom wrapper is trying to access to any metadata. In the error of the example you can see that it is accessing a folder called .hive-staging*. The solution is to configure Hive to store metadata in other location.

Symptom

Error message: "Could not initialize class org.xerial.snappy.Snappy"

Resolution

On Linux platforms, an error may occur when Snappy compression/decompression is enabled although its library is available from the classpath.

The native library snappy-<version>-libsnappyjava.so for Snappy compression is included in the snappy-java-<version>.jar file. When the JVM initializes the JAR, the library is added to the default temp directory. If the default temp directory is mounted with a noexec option, it results in the above exception.

One solution is to specify a different temp directory that has already been mounted without the noexec option, as follows:

```
-Dorg.xerial.snappy.tmpdir=/path/to/newtmp
```

9.1 HOW TO USE THE HADOOP VENDOR'S CLIENT LIBRARIES

In some cases, it is advisable to use the libraries of the Hadoop vendor you are connecting to (Cloudera, Hortonworks, ...), instead of the Apache Hadoop libraries distributed in this custom wrapper.

In order to use the Hadoop vendor libraries there is **no need to import the Distributed File System Custom Wrapper** as an extension as it is explained in the **Importing the custom wrapper into VDP** section.

You have to create the custom data sources using the **'Classpath' parameter** instead of the 'Select Jars' option.

Click Browse to select the directory containing the required dependencies for this custom wrapper, that is:

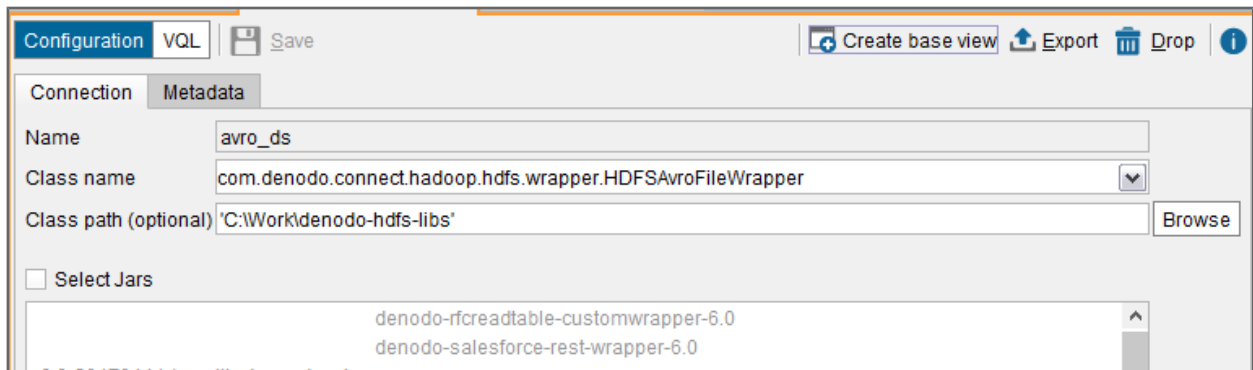

- The denodo-hdfs-customwrapper-\${version}.jar file of the dist directory of this custom wrapper distribution (highlighted in orange in the image below).
- The contents of the lib directory of this custom wrapper distribution, replacing the Apache Hadoop libraries with the vendor specific ones (highlighted in blue in the image below, the suffix indicating that they are Cloudera jars).

Here you can find the libraries for Cloudera and Hortonworks Hadoop distributions:

- Cloudera repository: <https://repository.cloudera.com/artifactory/cloudera-repos/org/apache/hadoop/>
- Hortonworks repository: <http://repo.hortonworks.com/content/repositories/releases/org/apache/hadoop/>

C:\Work\denodo-hdfs-libs directory

The screenshot shows the 'Configuration' tab of the Denodo Administration Tool. The 'Connection' tab is selected, and the 'Metadata' sub-tab is active. The configuration fields are as follows:

- Name:** avro_ds
- Class name:** com.denodo.connect.hadoop.hdfs.wrapper.HDFSAvroFileWrapper
- Class path (optional):** 'C:\Work\denodo-hdfs-libs' (with a 'Browse' button)
- Select Jars:** A checkbox that is currently unchecked.
- Jar List:** A list box containing two entries: 'denodo-rfcreadtable-customwrapper-6.0' and 'denodo-salesforce-rest-wrapper-6.0'.

At the top of the window, there are tabs for 'Configuration' and 'VQL', a 'Save' button, and a toolbar with 'Create base view', 'Export', 'Drop', and an information icon.

Distributed File System Data Source

! Note

When clicking **Browse**, you will browse the file system of the host where the Server is running and not where the Administration Tool is running.
